Introduction to Alzheimer’s disease

**What is Alzheimer’s**

AD is a multifactorial and heterogeneous neurodegenerative disorder, accounting for 60–80% of dementia cases\(^1,2\)

**Alzheimer’s pathology**

The presence of amyloid-beta and tau, synaptic failure, and neuronal dysfunction are common features of AD and are suggested to play a pivotal role in cognitive dysfunction\(^3–6\)

Amyloid deposition visualized on a PET scan\(^7\)

Image from Chapleau M, et al. (2022)\(^7\)

These pathological changes can begin many years before (~15–20 years) before the development of symptoms\(^4,5\)

---

Symptomatic pharmacologic treatments in Alzheimer’s disease

Symptomatic treatment temporarily ameliorates symptoms of AD, but does not affect the underlying disease pathology\(^1\)–\(^3\)

**Acetylcholinesterase inhibitors**

Approved for mild, moderate, and/or severe dementia due to AD

**NMDA receptor antagonists**

Approved for moderate-to-severe dementia due to AD

---

AD: Alzheimer’s disease; NMDA, N-methyl D-aspartate

AD is a neurodegenerative disease that causes problems with memory, language, and thinking. You may know these symptoms as dementia. Biological changes occur in the brain of people with AD. This includes a build-up of toxic protein clusters called amyloid plaques, which may lead to loss of brain function and the symptoms of AD. “Amyloid Related Imaging Abnormalities” or ARIA is a consequence of the presence of amyloid in cerebral blood vessels walls (cerebral amyloid angiopathy [CAA]). CAA can cause spontaneous ARIA in patients with AD. Monoclonal antibodies that target and remove toxic amyloid plaque from the brain to try and slow disease progression. Monoclonal antibodies that remove amyloid plaque increase the risk of ARIA.

What is ARIA?

- ARIA is a consequence of the presence of amyloid in cerebral blood vessel walls (cerebral amyloid angiopathy [CAA]).\(^1\) CAA can cause spontaneous ARIA in patients with AD and the risk of ARIA is increased with monoclonal antibodies that remove amyloid plaques\(^1\)

- Studies have suggested that ARIA-E and ARIA-H may be caused by disruption of vessels with CAA and the risk is increased by the clearance of Aβ from cerebral vessels, but other mechanisms are also hypothesized\(^2\)

- An Alzheimer’s Association workgroup defined the term “amyloid-related imaging abnormalities” or “ARIA” in AD, based on MRI findings which are subdivided into ARIA-E or ARIA-H\(^1\):
  - ARIA-E: parenchymal vasogenic edema or sulcal effusions detected on FLAIR sequences\(^3\)
  - ARIA-H: microhemorrhages, superficial hemosiderin deposition (superficial siderosis) detected on T2*GRE sequences\(^3\)

- Most cases of ARIA in patients treated with monoclonal antibodies that remove amyloid plaque are asymptomatic; however, ARIA-E may have concurrent symptoms such as headache, confusion, dizziness, and nausea; less likely, gait disturbances, visual impairment, and rarely seizures.\(^4\) ARIA can be serious, and life-threatening and may require intervention beyond withholding treatment to address symptoms\(^5\)

ARIA, amyloid-related imaging abnormalities; ARIA-E, ARIA-edema/effusion; ARIA-H, ARIA-hemosiderin/hemorrhage; FLAIR, fluid-attenuated inversion recovery; GRE, gradient-recalled echo

Interfering/removing the amyloid deposition in the brain that has built up over years can impact the vessel vasculature in the brain which can result in signal changes identifiable on MRI: “amyloid-related imaging abnormalities or ARIA”

ARIA is a known adverse reaction of monoclonal antibodies that remove amyloid plaque for AD

Monoclonal antibodies that remove amyloid

- Strategies to target and remove amyloid are based on our understanding that interfering with the underlying pathophysiologic mechanisms of the disease process could slow disease progression, but need to be initiated early in the course of disease given these changes begin in the early stages of disease

Amyloid-related imaging abnormalities

- Interfering/removing the amyloid deposition in the brain that has built up over years can impact the vessel vasculature in the brain which can result in signal changes identifiable on MRI: “amyloid-related imaging abnormalities or ARIA”

ARIA is a known adverse reaction of monoclonal antibodies that remove amyloid plaque for AD

Aβ, amyloid beta; ARIA: Amyloid-related imaging abnormalities; AD: Alzheimer’s Disease
ARIA-E and ARIA-H

ARIA is an umbrella term used to describe two types of imaging abnormalities¹

Pathophysiology
Hypothesized pathophysiology of ARIA

ARIA is a consequence of the presence of amyloid in cerebral blood vessel walls (cerebral amyloid angiopathy [CAA]), which can cause spontaneous ARIA in patients with AD. The increased occurrence of ARIA-E seen with treatments that remove amyloid plaques is thought to be due to the removal of vascular amyloid and disruption of amyloid in blood vessel walls. Other mechanisms are also hypothesized.

Aggregation of toxic Aβ species in the brain (amyloid plaques) and blood vessels (CAA) contributes to Alzheimer’s disease pathogenesis

After the introduction of monoclonal antibodies that remove amyloid plaque, vascular amyloid deposits begin to clear leading to increased vascular permeability

This loss of vascular integrity may be thought of as a transient exacerbation of the effects of CAA. The leakage of fluid could give rise to an increased signal detected on FLAIR images (ARIA-E), while leakage of red cells would result in ARIA-H

Limited evidence suggests that with repeated immunization and continued Aβ clearance, the integrity of vessels and efficiency of clearance can improve and risk of ARIA decreases

References:
Increased risk of ARIA-E and ARIA-H in carriers of APOE ε4

- APOE ε4 carriers (>60 years of age) have higher parenchymal and vascular Aβ load\(^1,2\)
- Therefore, when exposed to anti-Aβ monoclonal antibodies, they would experience a larger antibody-mediated shift in Aβ compared with non-carriers\(^3\)

- The presence of APOE ε4 alleles is one of the most robust known risk factors for ARIA-E\(^3\) and a proposed risk factor for ARIA-H\(^4\) occurrence in trials of monoclonal antibodies that remove amyloid plaque in patients with AD

- APOE ε4 carrier status is also a risk factor for spontaneously occurring ARIA-like events in microhemorrhage in the general population\(^5\), microhemorrhage among patients in memory clinics\(^6\), and CAA-ri\(^7\)

These findings support the hypothesis that vascular amyloid plays a key role in the induction of ARIA-E and ARIA-H\(^1,2\)

Clinical manifestations of ARIA
Clinical manifestations of ARIA

In most cases, ARIA is asymptomatic.\(^1\) Moreover, most cases occur early in the treatment course and decrease with increased duration of exposure\(^1,2\).

The most commonly reported symptoms of ARIA-E are transient and nonspecific and include headache, confusion, dizziness, nausea and neuropsychiatric symptoms; less frequent symptoms include fatigue, visual impairment, blurred vision, and gait disturbance\(^1,3\).

Infrequently, severe symptoms occur (e.g., encephalopathy, focal neurologic symptoms, seizures), requiring hospitalization and specific treatments (e.g., intensive care unit admission, electroencephalography, corticosteroids, antiepileptics).\(^1,4\) ARIA can be serious and life-threatening\(^4\).

Diagnosis of ARIA
ARIA risk factors

Main risk factors:

- **APOE ε4 carrier status**
- **Pre-treatment microhemorrhage**
- **Treatment with monoclonal antibodies that remove amyloid**

APOE, apolipoprotein E; ARIA, amyloid-related imaging abnormalities (includes ARIA-E and ARIA-H); ARIA-E, ARIA-edema/effusion; ARIA-H, ARIA-hemosiderin/hemorrhage;
Grading scale for determining radiographic severity of ARIA

ARIA-E, ARIA-H microhemorrhage, and ARIA-H superficial siderosis are each categorized by radiographic severity (mild to severe) based on the following criteria:

**ARIA-E**
Sulcal and/or cortical/subcortical FLAIR hyperintensity

**ARIA-H**
Superficial siderosis

**ARIA-H**
Number of new Microhemorrhages

ARIA, amyloid-related imaging abnormalities; ARIA-E, ARIA-vasogenic edema; ARIA-H, ARIA-microhemorrhages or hemosiderosis
ARIA-E or ARIA-H should be considered as the presumptive diagnosis when signal abnormalities on MRI are identified in patients recently exposed to monoclonal antibodies that remove amyloid plaque and in whom no evidence of any other inciting cause or underlying lesion can be found.

### Ischemic stroke
- MRI of ARIA-E edema may be mimicked by ischemic stroke.
- **Signs and symptoms** of ischemic stroke include: acute onset, hemiparesis, dysphasia or dysarthria, facial paresis, paresthesia, eye movement abnormalities, and visual field defects.
- Knowing if a patient is on monoclonal antibodies that remove amyloid helps with determining the diagnosis of ARIA.

### Subarachnoid hemorrhage
- ARIA-E effusion detected on MRI may be mimicked by SAH.
- Differentiating ARIA and SAH requires a systematic clinical and diagnostic approach.
- Subarachnoid hemorrhage typically presents with a number of signs and symptoms: severe headache accompanied by nausea or vomiting.
- Decreased level of consciousness and focal neurological signs can also be present.

### PRES
- PRES could resemble ARIA-E on imaging.
- PRES frequently develops from cytotoxic medication or disorders such as preeclampsia, sepsis, renal disease, or autoimmune disorders.
- Signs of PRES:
  - Encephalopathy, epileptic seizures, visual disturbances, and focal neurological deficits.
  - Less specific signs include:
    - Headache, nausea, vomiting.
  - In this case, clinical history is important for differentiating.
Management of ARIA
Management of ARIA

Refer to prescribing information of monoclonal antibodies that remove amyloid for monitoring and management guidelines of ARIA

Discuss ARIA and associated symptoms with patients and care partners before treatment initiation including the importance of MRI monitoring and seeking urgent evaluation in the case of ARIA clinical symptoms\(^1,2\)

MRI should be used to assess for ARIA symptoms where possible; CT scans can be deficient for detecting radiographic findings, particularly ARIA-H, owing to its relatively low spatial definition and resolution vs MRI\(^3\)

ARIA is most frequently detected on routine surveillance MRIs in patients who are clinically asymptomatic, highlighting the need for monitoring early in the course of therapy\(^4\)

In cases of severe or serious ARIA-E or ARIA-H, monitoring neurologic status closely and early empiric administration of high dose intravenous corticosteroids should be considered\(^1\)

ARIA, amyloid-related imaging abnormalities (due to ARIA-E and ARIA-H); ARIA-E, ARIA-edema/effusion; ARIA-H, ARIA-hemosiderin/hemorrhage; CT, computed tomography; MRI, magnetic resonance imaging.
